Physics

A structural correspondence study with the 5-Stage Model (Field · Wave · Edge · Vortex · Bundle)

Overview of the Study

- **Scope**: 11 major theories in physics
- **Research question**: Do theories of order generation in physics correspond structurally with the 5-Stage Model?
- **Results**: Strong correspondence in 7 cases (evidence strength: high), moderate correspondence in 3 cases, rejected in 1 case
- Physics is a domain that describes the process by which order emerges as an observable structure, and dense correspondence with the 5 stages was confirmed

---

Structural Correspondence Diagram

Overview of the 5-Stage Model

Stage	Definition
Field (ba)	Undifferentiated state. The initial condition in which neither direction nor structure has yet been determined
Wave (nami)	The stage of exploration in which multiple directions diverge and compete
Edge (en)	A state of tension in which opposing elements coexist without converging on either side. The place where they meet at a boundary, influence each other, and relationships emerge

Stage	Definition
Vortex (uzu)	The stage in which new coherence (order) spontaneously arises from within the tension
Bundle (taba)	The stage in which form is fixed and stabilizes as a reusable structure

---

Overview of Structural Correspondences

Theory	Core of 5-Stage Correspondence	Evidence Strength
Quantum field theory (QFT)	Quantum field → vacuum fluctuation → interaction → bound state/resonance → stable particle	High
BKT transition	Phase field → spin wave → vortex-pair binding → unbinding → post-transition phase	High
Abrikosov vortex lattice	Order parameter field → local destabilization → phase winding/interaction → vortex → lattice	High
Kibble–Zurek mechanism	High-symmetry phase → critical fluctuation → domain boundary → defect → scaling	High
Spontaneous symmetry breaking + Higgs mechanism	Symmetric vacuum → breaking → Goldstone → absorption/mass generation → spectrum	Moderate
Renormalization group	Critical system → fluctuation → RG flow → near fixed point → universality class	High
Laser oscillation	Disordered ensemble → population inversion → mode competition → stimulated emission chain → coherent light	High
Bénard convection	Quiescent fluid → buoyancy fluctuation → near criticality → convection cells → stable pattern	Moderate
Quantum decoherence	Superposition → environmental interaction → pointer selection → (no Vortex) → classical state	Moderate
Classical nucleation theory	Metastable phase → thermal fluctuation → critical nucleus interface → irreversible growth → stable phase structure	High

---

Key Entry 1: Abrikosov Vortex Lattice

- **Overview**: When a magnetic field is applied to a type-II superconductor, magnetic flux penetrates as individual quantum vortices, which then organize into a regular lattice
- **Structural correspondence**: This most clearly shows, in observable form, the transition from Vortex (individual flux lines) to Bundle (stable lattice structure)
- **Note**: Pinning effects that depend on the material may distort the lattice, so the ideal transition is not always realized

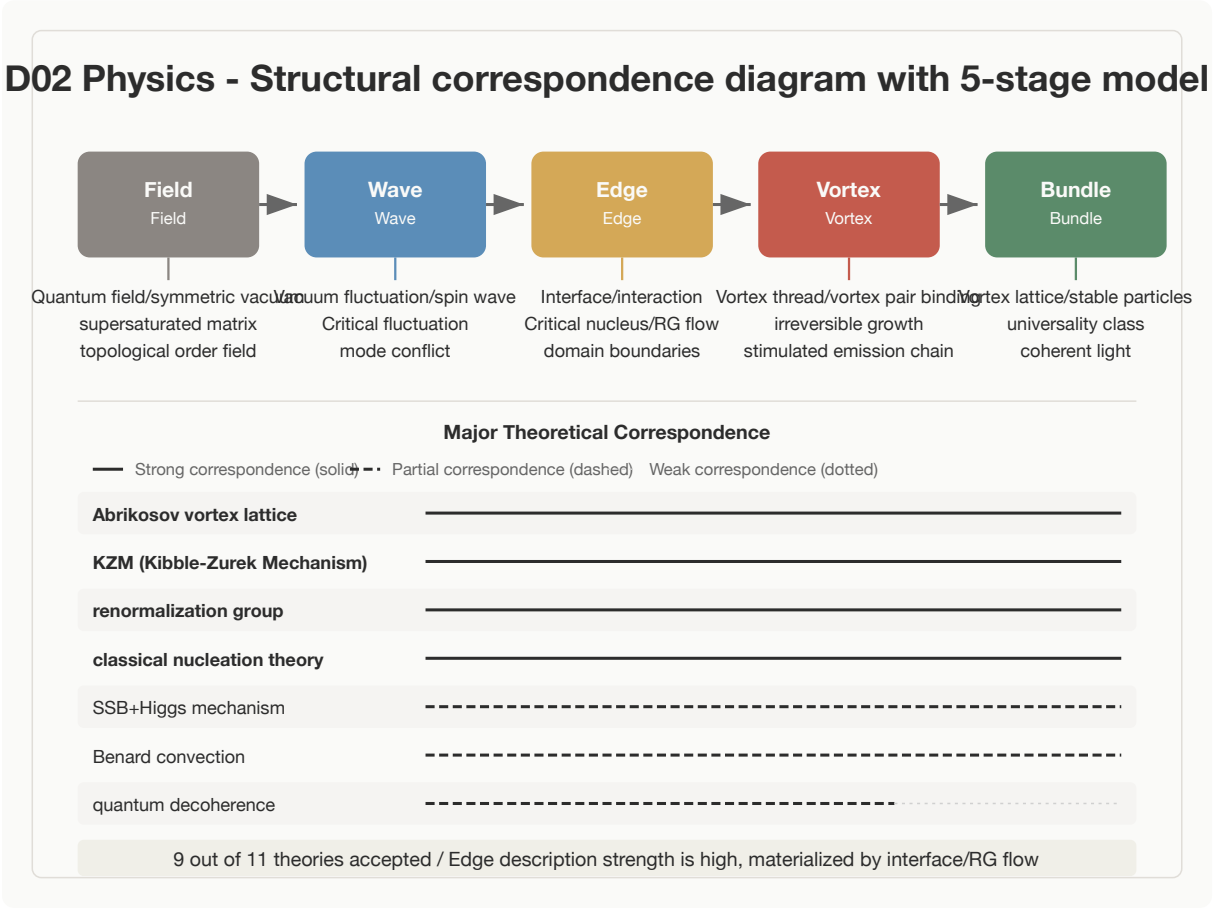

Figure 2: Structural correspondence diagram

Figure 3: Domain — Theory x 5-Stage Correspondence Matrix

Key Entry 2: Kibble–Zurek Mechanism

- **Overview**: During the early universe or material phase transitions, symmetry breaking proceeds in stages, constrained by causality. Based on the theories of Kibble (1976) and Zurek (1985)
- **Structural correspondence**: A distinctive feature is that the entire 5 stages can be explained on the basis of causality. High-symmetry phase (Field) → critical fluctuation (Wave) → domain boundary (Edge) → defect formation (Vortex) → scaling law (Bundle)
- **Note**: There is interpretive latitude in partitioning into 5 stages; one should be cautious that 5 stages is not the only possible partition

---

Key Entry 3: Renormalization Group

- **Overview**: A theory that systematically describes the behavior of physical quantities under scale transformations. Founded on Wilson's contributions (1971)
- **Structural correspondence**: Can be read as critical system (Field) → fluctuation (Wave) → RG flow (Edge) → reorganization near fixed point (Vortex) → universality class (Bundle)
- **Note**: Highly abstract and difficult on first encounter, but Edge can be clearly formulated as the operation of reorganizing relationships across scales

---

Cross-Cutting Patterns

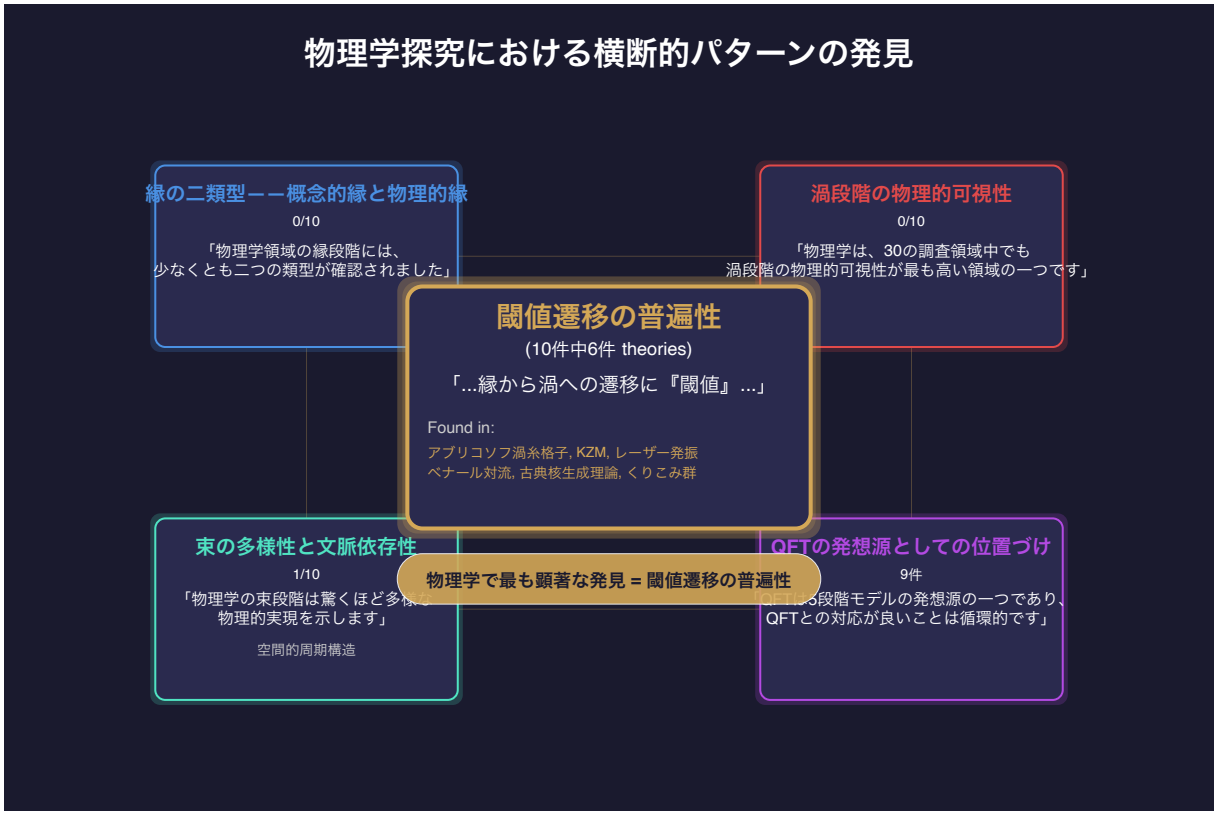

Figure 4: Domain — Cross-Cutting Patterns Diagram

- In physics, "Edge" is not abstract language but becomes a measurable quantity expressed as an interface, interaction, competition, or flow. This is the defining characteristic of this domain
- In 7 of the 11 theories, the descriptive strength of Edge is high, and a structure traceable as a causal chain through all 5 stages is found

- The 5 stages are not universal: stabilization pathways that bypass the Vortex stage, such as quantum decoherence, have also been confirmed

---

Open Questions

- Risk of over-generalizing "Edge": There is a danger of classifying something as Edge simply because it has interactions or an interface; rigorous determination based on three conditions — relational network, undecidability, and Vortex connectivity — is required
- Necessity of 5 stages: If vortex-free pathways such as decoherence are confirmed in large numbers, a revision from "always 5 stages" to "5 stages as the main pathway" is under consideration
- Source-of-inspiration bias: Because quantum field theory is one of the sources of inspiration for the 5-Stage Model, managing the risk of circular reasoning is necessary

---

Conclusion

- Physics is one of the domains in which structural correspondence with the 5-Stage Model has been confirmed most densely
- Particularly in the Abrikosov vortex lattice, the Kibble–Zurek mechanism, and the renormalization group, strong correspondences traceable as causal chains are found
- The "vortex-free pathway" of quantum decoherence remains as an important candidate counterexample to the universality of the 5 stages
